Â». Breakaway.Audio.Enhancer.1.30.02-atomicBS full.rar.Q: Accuracy when using Probabilistic backpropagation in Random Forest - Python I have trained a Random Forest classifier with gradient boosted trees using sklearn and the iris data set. I want to modify the implementation so that it uses probabilistic back propagation instead of ordinary back propagation. I am trying to do that using the sensitivity function as mentioned here. I would like to know what are the main differences between these two methods and how they can be applied in practical work? Are the results of the 2 methods different? A: Let's get straight to the point: the results are different but not much. Backpropagation methods basically compute the derivative, i.e. the sensitivity, of the loss with respect to the weights of the neural network. Let's consider the multilayer perceptron:  $x = \beta_1 W^T (Ax + b) + \beta_2 \text{relu}(W^T x + b) + \gamma_1$  where  $A$  is the matrix corresponding to the non-linearity and the output is of the form  $y = \gamma_2 \text{softmax}(W^T x + b)$  Let's now consider the evaluation of  $\frac{\partial y}{\partial W}$ , i.e.  $\frac{\partial y}{\partial \beta_1, \beta_2}$ : it's just a matrix multiplication  $y_i * (\gamma_2 A^T_i (W^T x_i + b) + \gamma_1)$  where the last two terms correspond to the normalization. Now, I want to introduce an error which is basically an important term in machine learning: the so-called overfitting. In essence, it means the inability of a trained network to generalize on unseen data. In a regression problem, this means that the model will predict the mean of the dataset, even if the data came from a different distribution. In classification, there are two common schemes: Classification with misclassification (classification error) which corresponds to  $1$  in the very first example. For instance, the network predicts  $0$  for the first example even
